

INTRODUCTION: 60056 is a friable, white rock (Fig. 1) that is probably a cataclastic anorthosite but may be a fragmental, polymict breccia. A thin coat of dark glass is present on some pieces. Apparently it was removed from its documented bag as a single piece but broke into many small fragments and fines during initial processing. 60056 was collected about 170 m southwest of the Lunar Module. Zap pits are absent.
